**Subject:** Re: June 2020 BCT meeting materials

Hi Eva,

The model does not consider the plume and looks at the mass discharges of contaminants and reaction products from the source area as a good metric that is available for many sites (e.g., a transect of monitoring wells just downgradient from the source). The model 'weeds' are in the remedial processes rather than water flow through a heterogeneous soil. The May 2017 sulfate reduction memo for ST012 provides an example of the 'weeds'. Modeling based on numerical solutions of groundwater flow tend to oversimplify the remedial processes (e.g., NAPL equilibrium, first order decay constants).

The purpose of the modeling is to consider governing processes for remediation of a NAPL source zone that yield a more objective evaluation of different approaches and outcomes. Each technology starts with the same conceptual model and site assumptions/properties. Even though the forecasts may not be completely accurate, if the model governing processes are relatively complete then the relative comparison of approaches is valid and valuable. We are adding features to allow modeling to be site-specific and include important field processes (e.g., back diffusion, mixing). Hope this helps. We are working to get a first publication out that will describe the weeds in a lot more detail.

Have a great weekend,

Bo

Some of the slides include discharge concentration - are you trying to estimate a mass discharge from the groundwater concentration data to predict the life of the plume? I feel like that is a wild guess, hope you can enlighten me.
